# CareerConnect - Sprint 2 AI Usage Log

Team Member: Wassim Amrani

Sprint: Sprint 2

Course: SOEN 341

## AI Log Entry 1

**Task ID/Title:**
Task 3 Preparation: Team Feature Integration and Merge Conflict Resolution

**Purpose of AI Use:**
To prepare the repository for Job Application Submission and Tracking by integrating the existing job-listing interface and my teammate's Dark Mode feature before building on them.

**Chat Link or Prompt/Response:**
Codex conversation: https://chatgpt.com/s/cx_6adeb4cdb76c81919df3db3c6818013f

**AI-Suggested Content:**
I asked Codex how to update the project after my teammates completed Task 2 and Dark Mode. Codex explained the pull-request workflow, helped interpret the branch's ahead/behind counts, and guided me through updating main and merging it into darkmode.

The merge produced a conflict in src/pages/index.html. Codex identified that Dark Mode had added a theme button to the homepage header, while Task 2 had replaced that header with a reusable component. It proposed keeping the shared header and Dark Mode script, adding the theme button to the shared header, and removing the conflict markers. The integration preserved both the job-listing interface and the existing theme feature.

**Validation:**
I supplied the git status and merge output to Codex. The terminal confirmed a clean main branch before the update and identified src/pages/index.html as the conflicted file. The earlier claim that GitHub could merge automatically was corrected when the actual merge reported a conflict. Later validation of the combined project included the full test suite, which Codex reported as passing.

**Decision:**
Accepted with modifications. Both teammates' features were preserved; the shared-header approach was retained for integration.

**Reflection:**
This showed me why an earlier merge-status message should not replace checking the current Git output. Codex helped explain the conflict, but the resolution needed to preserve both changes. The original job-listing and Dark Mode implementations remained my teammates' contributions.

## AI Log Entry 2

**Task ID/Title:**
Task 3: Job Application Submission and Tracking

**Purpose of AI Use:**
To implement the application-submission and tracking workflow, connect it to the existing job listings, and generate automated tests and supporting documentation. Codex was the only AI tool I used for this implementation.

**Chat Link or Prompt/Response:**
Codex conversation: https://chatgpt.com/s/cx_6adeb4cdb76c81919df3db3c6818013f

**AI-Suggested Content:**
I gave Codex the three Task 3 requirements: allow job seekers to apply for a posting, track the five required application statuses, and confirm successful submission. Codex's implementation summary describes persistent SQLite application records connected to the user and job, authenticated API endpoints, validation, duplicate-application prevention, and safe error handling.

New applications start with Applied. The implementation supports Applied, Under Review, Interview, Offered, and Rejected, with status-history and timestamp support. The My Applications interface includes filters, status counters, job links, timelines, empty states, and dark-mode support. Navigation links connect the job listings, job details, and application dashboard.

Codex also reported adding automated tests and acceptance-test and technical documentation.

**Validation:**
Codex reported tests covering application submission, persistence, duplicate prevention, user isolation, supported statuses, history, and invalid requests. Its final validation report stated that the complete project suite passed: 81 tests passed, 0 failed. This was the total suite result, not a count of tests added exclusively for Task 3.

The implementation was recorded in commit fefbae3 on codex/job-application-tracking, with the message "feat: add job application submission and tracking".

**Decision:**
Accepted with modifications. The implementation was retained, with a later correction to dark-mode styling on individual job pages.

**Reflection:**
Codex helped connect the database, API, and interface into one workflow. The useful checks went beyond whether the Apply button worked: duplicate submissions, persistence, and access to another user's applications also mattered. The reported full-suite result supported regression checking alongside the new feature tests.

# AI Log Entry 3

**Task ID/Title:**
Task 3 Scope Review: Application Statuses and Recruiter Integration

**Purpose of AI Use:**
To understand how recruiters would update application statuses and clarify the dependency between my application-tracking feature and the separate recruiter-management task.

**Chat Link or Prompt/Response:**
Codex conversation: https://chatgpt.com/s/cx_6adeb4cdb76c81919df3db3c6818013f

**AI-Suggested Content:**
I asked how the system would know which recruiter was responsible for a particular job. Codex explained the relationship between a recruiter's account, the postings they own, and the applications submitted to those postings. It proposed persistent account roles, a recruiter_id on jobs, an applicant dashboard, and an authorized status-update endpoint.

Codex also identified a limitation in the current integration: displaying a recruiter option during registration did not mean the backend already stored that role or assigned jobs to recruiter owners. It explained that ownership checks must be enforced by the backend, rather than relying only on hidden interface controls.

**Validation:**
The scope was compared with the Sprint 2 feature breakdown. Task 3 requires application submission, tracking of the five listed statuses, and submission confirmation. Task 4 separately covers recruiter posting management and viewing applications, with completion allowed in Sprint 3.

The conversation distinguishes status and history support from a completed recruiter-operated update workflow. I confirmed that recruiter management belonged to another teammate's task. Recruiter ownership and authorized status changes remained part of that separate integration work.

**Decision:**
Accepted as a design explanation. Implementation of recruiter roles, job ownership, and recruiter-controlled status updates was deferred to the responsible teammate's feature. My Task 3 work retained application storage, tracking, and status-history support for later integration.

**Reflection:**
This discussion clarified the difference between storing an application's status and providing an authorized way for a recruiter to change it. It also helped avoid building a competing account-role or ownership system. The remaining dependency should stay visible during integration so the team does not present the recruiter workflow as complete before it is connected and tested.

## AI Log Entry 4

**Task ID/Title:**
Task 3 Final Review: Dark-Mode Bug Fix and Version Control

**Purpose of AI Use:**
To correct a visible dark-mode issue on individual job-posting pages, validate the correction, and commit and push the completed work on its feature branch.

**Chat Link or Prompt/Response:**
Codex conversation: https://chatgpt.com/s/cx_6adeb4cdb76c81919df3db3c6818013f

**AI-Suggested Content:**
After the Task 3 implementation was committed locally, I reported: "dark mode doesnt work when youre in a job posting, fix it". Codex changed src/pages/assets/jobs.css to correct the job-page header card, description, At a glance panel, text, borders, tags, and disabled buttons. Its response also records adjustments to job-list cards and loading states.

Codex initially left the styling fix uncommitted, respecting my earlier instruction to commit the feature without pushing while I checked another issue. After I accepted the fix and requested a commit and push, it recorded the styling change as commit 681d674 and pushed the branch with the Task 3 commit fefbae3.

**Validation:**
My report of the job-page problem identified a visual defect after the initial feature work. Codex stated that it visually verified the corrected page and reran the complete suite, reporting all 81 tests passing. I then accepted the correction and instructed it to commit and push everything.

Codex reported that codex/job-application-tracking was synchronized with GitHub and the working tree was clean. It subsequently gave instructions for opening and merging a pull request into main. The branch was ready for the team's pull-request review.

**Decision:**
Accepted after correction. The CSS fix and Task 3 implementation were committed and pushed to the feature branch. The original Dark Mode feature remained credited to my teammate.

**Reflection:**
This was a useful reminder that passing automated tests does not guarantee that every page looks correct. Reporting the specific job-posting page led to a focused CSS correction. Keeping that fix in a separate commit also made it easier to distinguish the application feature from the integration adjustment.
